$\S 1$ REFLECT CWEB OUTPUT 1

May 16, 2016 at 15:13

1. This is a quick program to find all canonical forms of reflection networks for small n.

Well, when I wrote that paragraph I believed it, but subsequently I have added lots of bells and whistles because I wanted to compute more stuff. At present this code determines the number B_n of equivalence classes of reflection networks (i.e., irredundant primitive sorting networks); also the number of weak equivalence classes, either with (C_{n+1}) or without (D_{n+1}) anti-isomorphism; and the number of preweak equivalence classes (E_{n+1}) , which is the number of simple arrangements of n+1 pseudolines in a projective plane. For each representative of D_{n+1} it also computes the "score," which is the number of ways to add another pseudoline crossing the network.

If compiled without the NOPRINT switch, each member of B_n is printed as a string of transposition numbers, generated in lexicographic order. This is followed by * if the string is also a representative of C_{n+1} when prefixed by 01...n. And if the string is also a representative of D_{n+1} , you also get the score in brackets, followed by # if it is a representative of E_{n+1} . If not a representative of D_{n+1} , the symbol > is printed followed by the string of an anti-equivalent network.

If compiled with the DEBUG switch, you also get intermediate output about the backtrack tree and the networks generated while searching for anti-equivalence and preweak equivalence.

I wrote this program to allow n up to 10; but integer overflow will surely occur in $B_{10} \approx 2 \times 10^{10}$, if I ever get a computer fast enough to run that case. When n = 7, this program took 48 seconds to run, on January 12, 1991; the running time for n = 6 was 1 second, and for n = 8 it was 57 minutes. Therefore I made a stripped-down version to enumerate only B_n when n = 9.

```
#include <stdio.h>
```

This code is used in section 3.

2. There's an array a[1 ... n] containing k inversions; an index j showing where we are going to try to reduce the inversions by swapping a[j] with a[j+1]; and two arrays for backtracking. At choice-level l we set t[l] to the current j value, and we also set c[l] to 1 if we swapped, 0 if we didn't.

```
#define swap(j)
{ int tmp = a[j]; a[j] = a[j+1]; a[j+1] = tmp; } #define npairs 120 /* should be greater than 2\binom{n+1}{2} */#define ncycle 240 /* should be greater than 4\binom{n+1}{2} */
\langle \text{Global variables 2} \rangle \equiv
                /* number of elements to be reflected */
   int n;
   int a[10];
                     /* array that shows progress */
   int k:
                 /* number of inversions yet to be removed */
                /* current place in array */
   int j;
   int l;
                /* current choice level */
   int c[npairs];
                          /* code for choices made */
                          /* j values where choices were made */
   int t[npairs];
   int i, ii, iii;
                         /* general-purpose indices */
   int bn, cn, dn, en; /* counters for B_n, C_{n+1}, D_{n+1}, E_{n+1} */ int smin, smax; /* counters for "scores" */
   float stot;
                       /* grand total of scores */
See also sections 8 and 13.
```

The value of n is supposed to be an argument. #define abort(s) $\{ fprintf(stderr, s); exit(1); \}$ ⟨ Global variables 2⟩ main(argc, argv)int argc; /* number of args */**char** **argv; /* the args */ if $(argc \neq 2)$ $abort("Usage:_reflect_n\n");$ if $(sscanf(argv[1], "%d", &n) \neq 1 \lor n < 2 \lor n > 10)$ $abort("n_{\sqcup}should_{\sqcup}be_{\sqcup}in_{\sqcup}the_{\sqcup}range_{\sqcup}2..10!\n");$ $\langle \text{Initialize 4} \rangle;$ ⟨Run through all canonical reflection networks 5⟩; $printf("B=\%d, \Box C=\%d, \Box D=\%d, \Box E=\%d \n", bn, cn, dn, en);$ $printf("scores_min=%d,_max=%d,_mean=%.1f\n", smin, smax, stot/(float) dn);$ } 4. $\langle \text{Initialize 4} \rangle \equiv$ for $(j = 1; j \le n; j++) \ a[j] = n+1-j;$ $k=n*(n-1);\ k\not=2;$ c[0]=0; /* a convenient sentinel */ l = 1;j = n;bn = cn = dn = en = smax = 0;stot = 0.0;smin = 1000000000: This code is used in section 3. **5.** \langle Run through all canonical reflection networks $_5\rangle \equiv$ moveleft: j--;loop: if $(j \equiv 0)$ { if $(k \equiv 0)$ (Print a solution 7); (Backtrack, either going to loop or to finished when all possibilities are exhausted 6); if (a[j] < a[j+1]) goto moveleft; t[l] = j;c[l++] = 0;

This code is used in section 3.

goto moveleft;

finished:;

 $\S 6$ Reflect CWEB output 3

```
6. (Backtrack, either going to loop or to finished when all possibilities are exhausted 6) \equiv
  while (c[--l]) {
     j = t[l];
     swap(j);
  if (l \equiv 0) goto finished;

#ifndef NOPRINT
     putchar('\n');
\#\mathbf{endif}
     bn ++;
This code is used in section 5.
```

8. Here's part of the program I wrote after getting the above to work. The idea is to see if the almost-canonical form for an (n+1)-element network is weakly equivalent to any lexicographically smaller almost-canonical forms. If not, we print an asterisk, because it represents a new weak equivalence class.

The forms are kept in locations r through r + n(n+1)/2 - 1 of array b, which starts out like t but with the transpositions $1, 2, \ldots, n$ prefaced. End-around shifts are performed (advancing r by 1 each time) until the original form appears again.

```
\langle Global variables 2\rangle +\equiv
int b[ncycle]; /* larger array used for testing weak equivalence */
int r, rr; /* the first and last active locations in b */
int d[npairs]; /* copy of the present network */
int rrr; /* \binom{n+1}{2} */
```

```
9. \langle Check if it gives a new CC system on n+1 elements 9\rangle \equiv
  for (rr = 0; rr < n; rr ++) b[rr] = rr + 1;
  for (i = 1; i < l; i ++)
     if (c[i]) {
       b[rr] = d[rr] = t[i];
        rr ++;
  d[rr] = 1;
                  /* sentinel */
  rrr = rr;
  r = 0;
  while (1) {
     \langle Shift the first transposition to the other end 10\rangle;
     if (b[r] \equiv 1) \(\text{Test lexicographic order; break if equal or less 11}\);
  }
This code is used in section 7.
10. \langle Shift the first transposition to the other end _{10}\rangle\equiv
  j = n - b[r++];
  for (i = rr + +; b[i-1] < j; i--) b[i] = b[i-1];
  b[i] = j + 1;
This code is used in section 9.
11. \langle Test lexicographic order; break if equal or less _{11}\rangle\equiv
                  /* sentinel, is less than the 1 we put in d */
     b[rr] = 0;
     for (i = r + n; b[i] \equiv d[i - r]; i++);
     if (b[i] < d[i-r]) {
  if (i \equiv rr) { /* total equality */
#ifndef NOPRINT
          putchar('*');
\#endif
          \langle Make the big test for pre-weak equivalence 12\rangle;
        break;
This code is used in section 9.
```

 $\S12$ REFLECT CWEB OUTPUT 5

12. Well, after I got that going I couldn't resist continuing until I had all simple arrangements of pseudolines enumerated. That requires looking at another $\binom{n+1}{2}$ cases to see if they are weakly equivalent to anything seen before.

```
And, surprise, it also meant testing for anti-isomorphism.
\langle Make the big test for pre-weak equivalence 12 \rangle \equiv
  \langle \text{ Reset } b \text{ to a double cycle } 14 \rangle;
   Test the reverse of b for weak equivalence; goto done if weakly equivalent to a previous case 15;
   Compute the score for this weak equivalence/antiequivalence class rep 22;
  for (r = 0; r < rrr; r ++) {
     \langle Move the "pole" into the cell preceding the first transposition module 20\rangle;
     for (ref = 0; ref < 2; ref ++) {
       if (ref \equiv 0)
          for (i = 0; i < rrr; i++) y[i] = x[i];
       else \langle Replace the present x by the reverse of y 16\rangle;
       (If the new network is weakly equivalent to a lexicographically smaller one, goto done 17);
#ifndef NOPRINT
  putchar('#');
                      /* a new preweak class, not related to anything earlier */
#endif
  en ++;
done:;
```

13. For this part of the program we use an array x analogous to b; also variables s and ss analogous to r and rr; also an array e analogous to d.

```
(Global variables 2) +\equiv
int x[ncycle]; /* network to be tested for weak equivalence */
int m; /* largest element in x so far */
int y[npairs]; /* elements to be carried around to the right as x is formed */
int jj; /* the number of elements in y */
int s, ss; /* the active region of x */
int e[npairs]; /* starting point */
int rep; /* number of repetitions */
int ref; /* number of reflections */
```

14. At this point i-r points just past the end of the d data, and the first n entries of b are still equal to $1, 2, \ldots, n$. The network we construct here is not necessarily in canonical form.

```
 \langle \text{Reset } b \text{ to a double cycle } 14 \rangle \equiv \\ rr = i - r; \\ \textbf{for } (i = n; \ i < rr; \ i++) \ b[i] = d[i]; \\ \textbf{for } (\ ; \ i < rr + rr; \ i++) \ b[i] = n+1-b[i-rr]; \\ \text{This code is used in section } 12.
```

This code is used in section 11.

15. One nice thing is that reflection and turning upside down preserve canonicity when we do both simultaneously.

```
\langle Test the reverse of b for weak equivalence; goto done if weakly equivalent to a previous case 15 \rangle \equiv
  for (i = 0; i < rrr; i++) x[rrr - 1 - i] = n + 1 - b[i];
  s = 0; ss = rrr;
  while (x[s] > 1) (End-around shift x 19);
  for (i = s + n; i < ss; i++) e[i - s] = x[i];
  e[rrr] = 1; /* another sentinel */
  while (1) { x[ss] = 0;
                            /* sentinel */
  for (i = s + n; x[i] \equiv d[i - s]; i++);
  if (i \equiv ss) break; /* anti-isomorphic to itself */
  if (x[i] < d[i - s]) {
                          /* anti-isomorphic to previous guy */
#ifndef NOPRINT
    putchar('>');
    for (i = s + n; i < ss; i++) putchar(x[i] + '0' - 1);
    goto done;
  do \langle End-around shift x 19\rangle
  while (x[s] > 1);
  x[ss] = 0;
  for (i = s + n; x[i] \equiv e[i - s]; i++);
  if (i \equiv ss) break; /* anti-isomorphic to some future guy */
  }
This code is used in section 12.
     \langle Replace the present x by the reverse of y 16\rangle \equiv
    s = 0; ss = rrr;
    while (x[s] > 1) \langle End-around shift x 19\rangle;
#ifdef DEBUG

This code is used in section 17.

19. \langle End-around shift x 19 $\rangle \equiv \{$ j = n - x[s++];for (i = ss + +; x[i-1] < j; i--) x[i] = x[i-1]; x[i] = j + 1;

This code is used in sections 15, 16, and 17.

20. The only somewhat tricky operation comes in here. We use the fact that the first '1' in a canonical network is always immediately followed by $2, \ldots, n$; reversing these, decreasing the previous by 1, and increasing the remaining by 1 takes that line around the pole. This operation might require carrying some transpositions around from left to right.

```
\langle Move the "pole" into the cell preceding the first transposition module 20 \rangle \equiv
  \langle If debugging, print the active region of b \ 24 \rangle;
  s = 0; ss = rrr;
  iii = jj = 0;
  x[0] = m = rep = b[r];
  rr = r + rrr;
  for (i = r + 1; i < rr; i ++) {
     j = b[i] - 1;
     (Insert the value j + 1 canonically into x \ge 1);
  for (i = 0; iii < rrr - 1; i++) {
     j = n - 1 - y[i];
     (Insert the value j + 1 canonically into x \ge 1);
  \langle If debugging, print the active region of x \ 25 \rangle;
  while (rep ---) {
     m=0;
     for (i = 0; x[i] \neq 1; i++) {
       if (x[i] > m) m = x[i];
     iii = i - 1;
     jj=0;
     for (j = n - 1; j \ge 0; j --)
       if (j \equiv 0 \land i \equiv 0) {
          x[0] = m = 1;
          iii = 0;
       else (Insert the value j + 1 canonically into x \ge 21);
     {\bf for} \ (i \ += n; \ i < rrr; \ i +\!\!\!+) \ \{
        j = x[i];
        (Insert the value j + 1 canonically into x \ge 1);
     for (i = 0; iii < ss - 1; i++) {
       j = n - 1 - y[i];
        (Insert the value j + 1 canonically into x \ge 1);
     \langle If debugging, print the active region of x \ 25 \rangle;
  }
This code is used in section 12.
```

 $\S21$ REFLECT CWEB OUTPUT 9

21. We must carry over items that exceed m, which denotes the maximum value stored so far, because we want the first element of x[0] to remain in place.

```
 \begin{split} &\langle \text{Insert the value } j+1 \text{ canonically into } x \text{ 21} \, \rangle \equiv \\ & \text{if } (j>m) \ y[jj++]=j; \\ & \text{else } \{ \\ & \text{if } (j\equiv m) \ m++; \\ & \text{for } (ii=++iii; \ x[ii-1]< j; \ ii--) \ x[ii]=x[ii-1]; \\ & x[ii]=j+1; \\ & \} \end{split}
```

This code is used in section 20.

22. The score is computed in several passes, although I do know how to do it in linear time. Since the x array is currently unused, I store in x[i] the score for the cell following transposition i.

```
\langle Compute the score for this weak equivalence/antiequivalence class rep 22\rangle \equiv
  dn ++;
  rr = rrr + rrr;
  for (i = 0; i < rr; i++) x[i] = 1;
  for (j=2; j \le n; j++) (Fill in the cell counts x[i] for cases when b[i]=j 23);
  { register int score = 0;
    for (i = 0; i < rr; i++)
       if (b[i] \equiv n) score += x[i];
    stot += (float) score;
    if (score > smax) smax = score;
    if (score < smin) smin = score;
#ifndef NOPRINT
    printf(" [\%d]", score);
#endif
  }
This code is used in section 12.
```

23. As we fill the cell counts, we assume that x[ii] is the previous cell having b[i] = j. We assume that $b[i] \equiv i + 1$ for $0 \le i < n$.

```
 \langle \text{Fill in the cell counts } x[i] \text{ for cases when } b[i] = j \text{ 23} \rangle \equiv \\ \{ \text{ int } acc = 0; \\ \text{ int } p; \quad /* \text{ most recent } x[i] \text{ when } b[i] = j - 1 \text{ } */\\ ii = rr; \\ \text{ for } (i = 0; \ i < rr; \ i++) \text{ } \{ \text{ register int } delta = j - b[i]; \\ \text{ if } (delta \equiv 0) \text{ } \{ \\ x[ii] = acc; \\ ii = i; \\ acc = p; \\ \} \\ \text{ else if } (delta \equiv 1) \text{ } \{ \\ p = x[i]; \\ acc + = p; \\ \} \\ \} \\ x[ii] = acc + x[rr]; \\ \}
```

This code is used in section 22.

```
24. \langle If debugging, print the active region of b \ 24 \rangle \equiv
#ifdef DEBUG
   printf("\n>");
   for (m = r; m < r + rrr; m++) putchar(b[m] + '0' - 1);
This code is used in section 20.
25. (If debugging, print the active region of x \ge 5)

REFLECT NAMES OF THE SECTIONS 11

```
(Backtrack, either going to loop or to finished when all possibilities are exhausted 6) Used in section 5.
 Check if it gives a new CC system on n+1 elements 9 Used in section 7.
 Compute the score for this weak equivalence/antiequivalence class rep 22
                                                                                    Used in section 12.
 End-around shift x 19 \rightarrow Used in sections 15, 16, and 17.
 Fill in the cell counts x[i] for cases when b[i] = j 23 \quad Used in section 22.
 Global variables 2, 8, 13 \ Used in section 3.
 If debugging, print the active region of b 24 Used in section 20.
 If debugging, print the active region of x \ge 5 Used in sections 16, 17, and 20.
 If the new network is weakly equivalent to a lexicographically smaller one, goto done 17 \rangle Used in section 12.
(If the x network is weakly equivalent to an earlier one, goto done; if weakly equivalent to the present one,
    goto okay 18 \rangle Used in section 17.
\langle \text{Initialize 4} \rangle Used in section 3.
(Insert the value j + 1 canonically into x \ge 1) Used in section 20.
(Make the big test for pre-weak equivalence 12) Used in section 11.
 Move the "pole" into the cell preceding the first transposition module 20 \rangle Used in section 12.
 Print a solution 7 Used in section 5.
 Replace the present x by the reverse of y 16 \ Used in section 12.
 Reset b to a double cycle 14 \rangle Used in section 12.
 Run through all canonical reflection networks 5 Used in section 3.
 Shift the first transposition to the other end 10 Used in section 9.
 Test lexicographic order; break if equal or less 11 \( \) Used in section 9.
\langle Test the reverse of b for weak equivalence; goto done if weakly equivalent to a previous case 15\rangle Used in
    section 12.
```
